Abstract—This research focuses on enhancing the production of ethylenediamine (EDA) through the catalytic reaction of monoethanolamine (MEA) and ammonia (NH_3) in a heterogeneous plug flow reactor (PFR) using Aspen HYSYS simulation. The process involves a primary reaction converting MEA to EDA and a secondary reaction yielding diethylenetriamine (DETA) as a byproduct. Raney Nickel serves as the catalyst, while key operational parameters—temperature, pressure, and feed ratios—are systematically adjusted to evaluate their impact on yield, selectivity, and conversion efficiency. The study identified optimal conditions for achieving a maximum EDA yield of 94.4% at 150°C, 6000 kPa, and a 14:1 ammonia-to-MEA molar ratio, effectively minimizing byproduct formation. The findings underscore the effectiveness of Aspen HYSYS as a tool for simulating and optimizing complex chemical processes, providing critical insights into reactor design and operational control. Sensitivity analyses reveal increased pressure improves conversion rates, while lower temperatures enhance EDA selectivity over DETA formation. These insights advance the understanding of heterogeneous catalytic processes and offer strategies for improving EDA production efficiency on an industrial scale. In addition to promoting sustainable chemical manufacturing, the results offer practical recommendations for minimizing environmental impact and optimizing process efficiency. Future efforts should prioritize experimental validation, explore alternative catalysts, and investigate innovative reactor designs to further refine and scale up the production of EDA, aligning with industrial and environmental goals.

Keywords—Ethylenediamine; Monoethanolamine; plug flow reactor; simulation; HYSYS.

I. INTRODUCTION

Ethylenediamine (EDA) is a multifunctional compound that finds widespread application in the synthesis of chelating agents, pharmaceuticals, and polymeric materials [1]-[8]. The increasing global demand for EDA has prompted significant research into optimizing its synthesis to improve yield, efficiency, and sustainability [9]-[12]. Among the available methods for producing EDA, the reductive amination of *monoethanolamine* (MEA) with ammonia, catalyzed by heterogeneous materials like Raney Nickel, has emerged as a promising pathway due to its simplicity and efficiency.

At present, there are three main techniques utilized for the synthesis of ethylene amines. The first method involves the reaction of ethylene dichloride with ammonia, resulting in a comprehensive array of *ethylenamine* products. The second method is the reductive amination of *monoethanolamine*, which predominantly yields lighter ethylene amines such as

ethylenediamine (EDA). Lastly, the catalytic reaction between *Monoethanolamine* (MEA) and Ethylenediamine facilitates the production of higher-order *ethylene amines* [13]-[16]. Kinetic constants for the production of Ethylenediamine are accessible [17], [18].

This work aims to investigate the reductive amination of *Monoethanolamine* (MEA) with Ammonia (NH_3) under a heterogeneous catalyst (referred to as the "RA Process"). Figures 1 and 2 illustrate the typical production of ethylenediamine (EDA) through the RA process [19]. The recommended catalysts for this procedure are Raney nickel or cobalt, copper, modernity, chromite, platinum, osmium, palladium, and others [9], [20]-[23].

In recent years, attention has switched towards improving reactor design and operating conditions to optimize yield while minimizing byproduct formation [3], [24]-[26]. The synthesis of EDA is a complicated process that involves both primary and secondary reactions. The primary response transforms MEA to EDA, while the secondary reaction yields

Diethylenetriamine (DETA), an undesirable byproduct. Controlling operating variables such as temperature, pressure,

and catalyst characteristics is critical for increasing EDA selectivity while reducing DETA production.

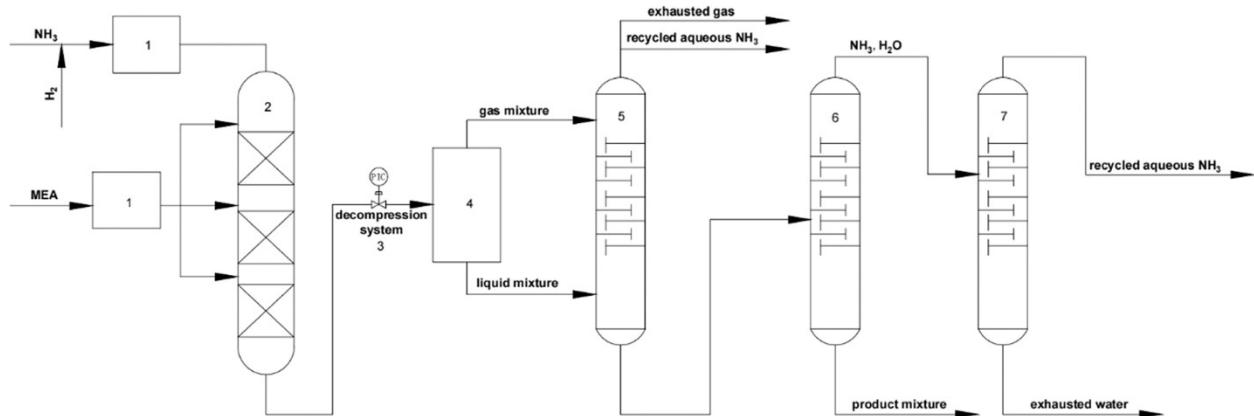

Fig. 2 Schematic diagram of the apparatus: 1, heater; 2, reactor; 3, valve; 4, gas separator; 5–7, distillation column. Source: [9].

The Plug Flow Reactor (PFR) is commonly employed for heterogeneous catalytic reactions, including EDA production, due to its ability to sustain high conversion rates, manage heat transfer effectively, and enable precise control over reaction kinetics [27]-[32]. However, optimizing PFR performance for EDA production remains a complex challenge. This is primarily because synthesis involves primary reactions to produce EDA and secondary reactions that generate byproducts such as diethylenetriamine (DETA), which reduce process selectivity and economic efficiency. Effective reactor design and operational optimization are critical for enhancing EDA yield and minimizing byproduct formation.

Fluid dynamics, reactor size, and catalyst activity are some of the variables that affect PFR performance in heterogeneous catalysis. Numerous studies have examined optimizing PFRs for various chemical processes, emphasizing how crucial reactor design is to attaining high yield and selectivity.

Several studies have explored the chemistry and catalysis involved in EDA production [9], [33], [34]. For instance, Ma et al. [21] analyzed the effects of Ni particle size on the amination of MEA, and Xie et al. [22] compared the catalytic efficiency of nickel and cobalt for similar processes. While these studies have contributed valuable insights into catalytic

behavior, they often focus on catalyst performance rather than the holistic optimization of the production process. Similarly, research on PFR applications has examined general principles of reactor performance but lacks targeted analyses for EDA synthesis. The interactions among critical parameters, such as temperature, pressure, and feedstock ratios, and their combined impact on yield and selectivity remain underexplored.

Simulation tools like Aspen HYSYS have been widely used in the chemical industry for process design and optimization due to their robust capabilities in modeling complex reaction systems [35]-[45]. However, their application to optimize PFR performance for EDA production is not well-documented in existing literature. This represents a significant gap in leveraging advanced simulation to improve EDA's industrial-scale production efficiency. Aspen HYSYS advanced thermodynamic packages, reaction kinetics modeling, and sensitivity analysis tools make it ideal for studying heterogeneous catalytic processes like EDA synthesis [46]-[48]. This research uses Aspen HYSYS to evaluate the trade-offs between operating conditions, product yield, and byproduct formation, offering a practical approach to achieving optimal reactor performance. This study aims to address these gaps by evaluating the performance of a PFR in

EDA production through detailed simulations using Aspen HYSYS. The research systematically investigates the impact of key operational parameters—including temperature, pressure, and the ammonia-to-MEA feed ratio—on reactor performance, with the goal of maximizing EDA yield and minimizing DETA formation.

The novelty of this research lies in its integration of advanced simulation tools to analyze and optimize the EDA synthesis process. By conducting a comprehensive sensitivity analysis and identifying optimal reactor conditions, this study advances knowledge in reactor design and process control and offers actionable insights for improving the scalability and sustainability of EDA production.

II. MATERIALS AND METHOD

A. Chemicals and Catalysts

In this study, Ethylenediamine (EDA) is produced through the catalytic reaction of *Monoethanolamine* (MEA) with Ammonia (NH_3). Raney Nickel, a catalyst known for its high activity and stability in hydrogenation reactions, is employed in this process. Raney Nickel is crucial for enhancing the conversion of MEA to EDA while reducing the formation of by-products like diethylenetriamine (DETA).

B. Simulation Setup

The process simulation was conducted utilizing Aspen HYSYS V14, a process modeling software extensively employed in the chemical industry for dynamic and steady-state simulations. This software was selected due to its comprehensive thermodynamic package and ability to model complex chemical reactions accurately.

C. Reactor Model

The reactor used in the simulation is a plug flow reactor (PFR), which is suitable for heterogeneous catalytic processes. The PFR model in HYSYS was chosen because of its ability to handle variations in concentration and temperature along the reactor length, providing a more accurate representation of industrial reactor conditions.

D. Thermodynamic Package

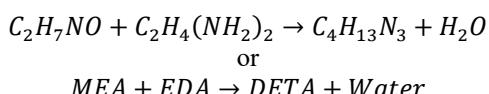

The NRTL equation of state was employed as the thermodynamic package to calculate the system's phase equilibria and thermodynamic properties. This equation of state is appropriate for the high-pressure systems typically involved in EDA production.

E. Reaction Kinetics

The primary reaction modeled in the simulation is the conversion of MEA to EDA, which the following reaction can represent:

The secondary reaction, which leads to the formation of DETA, was also included in the model:

The reaction kinetics were defined using rate expressions based on literature values (Table 1), with the activation energy and pre-exponential factors for both reactions taken from relevant studies.

F. Operating Conditions

The simulation was conducted under various operating conditions to identify the optimal parameters for maximizing EDA yield. The key parameters varied include (1) Temperature (the reactor temperature was varied between 150°C and 250°C to assess its impact on the reaction rate and product distribution), (2) Pressure (the pressure within the reactor was adjusted from 2000 kPa to 6000 kPa to evaluate its influence on the reaction equilibrium and conversion rates), (3) NH_3 to MEA ratio was modified to study its effect on the overall reaction rate and selectivity.

G. Data Analysis

The output data from the HYSYS simulation, including the molar flow rates of EDA, MEA, and byproducts, were analyzed to determine the yield and conversion rates. Sensitivity analyses were performed to understand each parameter's influence on EDA production. Graphs and tables were generated to present the relationship between the operating conditions and the reactor performance.

H. Optimization Procedure

A systematic approach was used to optimize the reactor conditions. Initially, a baseline simulation was conducted using standard operating conditions derived from industrial practices. Following this, individual parameters were varied systematically to observe their impact on the yield and selectivity. The optimal conditions were identified based on the highest EDA yield with minimal byproduct formation.

I. Block Diagram

The block diagram for this process is shown in Figure 3. The figure represents a Plug Flow Reactor (PFR-100), a chemical reactor used for continuous processing. MEA (*Monoethanolamine*) and Ammonia are fed into the reactor. Two streams exit the reactor—one labeled "Products," representing the desired chemical outcome, and another labeled "Q," referring to heat transfer to maintain the reactor temperature at isothermal conditions. This setup is commonly used in chemical engineering to ensure efficient reaction progression by allowing reactants to move through the reactor in a streamlined, sequential manner.

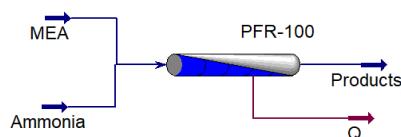

Fig. 3 HYSYS Process Flow Diagram for Ethylenediamine Production in Plug Flow Reactor

III. RESULTS AND DISCUSSION

A. Simulation Outcomes

The Aspen HYSYS simulation provided comprehensive insights into ethylenediamine (EDA) production under varying reactor conditions. The molar flow rates of EDA,

unreacted monoethanolamine (MEA), ammonia (NH_3), and the byproduct diethylenetriamine (DETA) were analyzed. As the simulation explored changes in temperature, pressure, and the ratio of ammonia to *monoethanolamine*, key trends emerged regarding the yield and selectivity of the reactions. Table 1 provides the basis for the simulation.

TABLE I
BASIS CONDITION FOR SIMULATION

Variable	Value, Unit
$T_{\text{operating}}$	150°C to 250°C
$P_{\text{operating}}$	2000 kPa to 6000 kPa
A_1 (main reaction)	$5.1271 \times 10^5 \text{ kg mole/m}^3\text{.h}$
E_1 (main reaction)	14200 kJ/kg mole
A_2 (side reaction)	$3.4321 \times 10^5 \text{ kgmole/m}^3\text{.h}$
E_2 (side reaction)	11300 kJ/kg mole
Molar flow MEA inlet	4000 kg mole/h
Molar flow Ammonia inlet	10000 kg mole/h
Raney catalyst density	6500 kg/m ³
Raney catalyst sphericity	1
Type of reactor	Plug Flow Reactor (PFR)
Number of segments	20
Length	12 m
Diameter of reactor	6 m
Void fraction	0.1

B. Temperature Effect

The temperature range between 150°C and 250°C was systematically explored. It was observed that, while higher temperatures typically increase reaction rates, the yield of EDA peaked at around 150°C. Beyond this point, increasing the temperature reduced yield due to increased byproduct formation, particularly DETA (see Figs 4, 5, and Table 2). This behavior suggests that a balance must be maintained between maximizing conversion rates and suppressing unwanted side reactions.

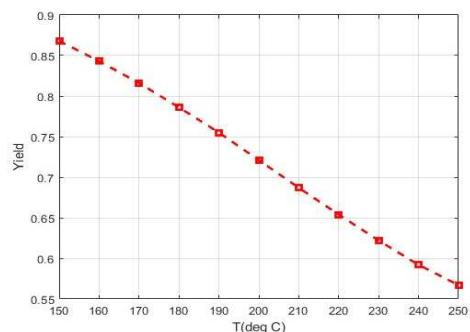

Fig. 4 Yield vs Temperature at 2000 kPa

Compared to previous studies by Maxwell [49], the results align with observations that lower temperatures favor selectivity towards lighter *ethylene-amines* like EDA. The simulations revealed that an optimal yield of 86.8% was achieved at 150°C and 2000 kPa, confirming the significant role temperature plays in reaction optimization [49].

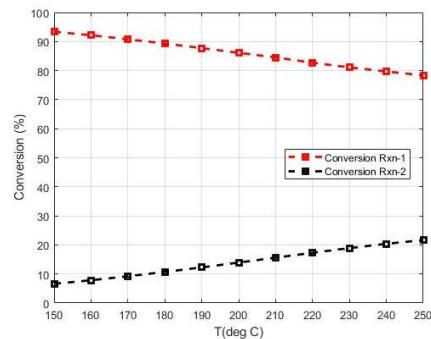

Fig. 5 Conversion vs Temperature at 2000 kPa

TABLE II
EFFECT OF TEMPERATURE

T (°C)	P (kPa)	MEA inlet (kg mole/h)	NH ₃ inlet (kg mole/h)	Product (kg mole/h)	EDA in Product (kg mole/h)	NH ₃ excess (kg mole/h)	Yield	DETA in Product (kg mole/h)
150	2000	4000	10000	14000	3472.000	6263.600	0.868	263.200
160	2000	4000	10000	14000	3372.600	6314.000	0.843	313.600
170	2000	4000	10000	14000	3262.000	6368.600	0.816	368.200
180	2000	4000	10000	14000	3144.400	6427.400	0.786	428.400
190	2000	4000	10000	14000	3018.400	6490.400	0.755	491.400
200	2000	4000	10000	14000	2885.400	6557.600	0.721	557.200
210	2000	4000	10000	14000	2749.600	6624.800	0.687	624.400
220	2000	4000	10000	14000	2616.600	6692.000	0.654	691.600
230	2000	4000	10000	14000	2486.400	6756.400	0.622	756.000
240	2000	4000	10000	14000	2368.800	6815.200	0.592	814.800
250	2000	4000	10000	14000	2266.600	6867.000	0.567	866.600

C. Pressure Effect

Pressure also significantly influences the reaction kinetics and yield. As the reactor pressure increased from 2000 kPa to 6000 kPa, the yield of EDA rose steadily, peaking at 94.4% at

6000 kPa (Table 3, Figs. 6 and 7). This increase is attributed to the positive effect of pressure on shifting the equilibrium towards product formation, as per Le Chatelier's principle. These findings are consistent with existing literature on pressure optimization in amination reactions.

TABLE III
EFFECT OF PRESSURE

T (°C)	P (kPa)	MEA inlet (kg mole/h)	NH ₃ inlet (kg mole/h)	Product (kg mole/h)	EDA in Product (kg mole/h)	NH ₃ excess (kg mole/h)	Yield	DETA in Product (kg mole/h)
150	2000	4000	10000	14000	3472.000	6263.600	0.868	263.200
150	3000	4000	10000	14000	3613.400	6193.600	0.903	193.200
150	4000	4000	10000	14000	3693.200	6153.000	0.923	154.000

150	6000	4000	10000	14000	3777.200	6111.000	0.944	110.600

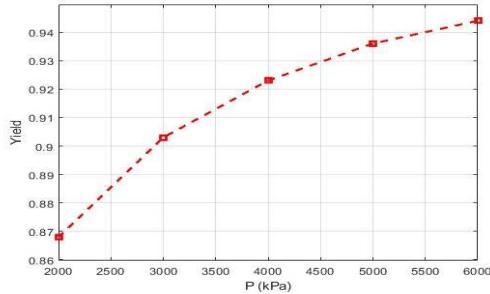

Fig. 6 Yield vs Pressure at T=150 C

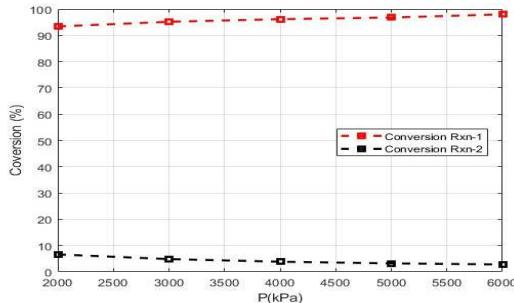

Fig. 7 Conversion vs Pressure at T=150 C

D. Selectivity and Byproduct Formation

Selectivity towards EDA is a crucial performance measure in the catalytic process. The formation of DETA, a byproduct, competes with the desired EDA production. The simulation data shows that optimizing temperature and pressure, combined with careful catalyst management, can suppress the secondary reaction that leads to DETA formation. The optimal conditions of 150°C, 6000 kPa, and the correct catalyst loading achieved the highest selectivity, minimizing DETA to negligible levels. At the identified optimal conditions (150°C, 6000 kPa, and optimal catalyst loading),

the selectivity towards EDA was maximized, with DETA formation kept to a minimum (Figs. 8 and 9). This indicates that careful control of operating parameters is essential for achieving high selectivity in the industrial production of EDA.

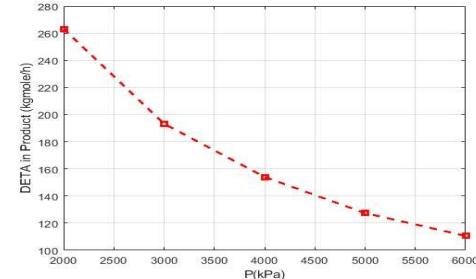

Fig. 8 DETA in Product vs P at 150 C

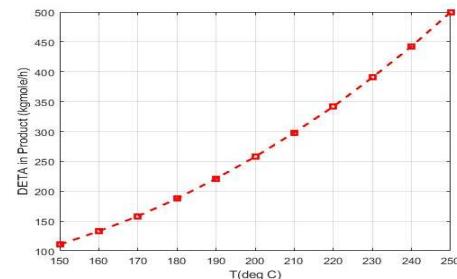

Fig. 9 DETA in Product vs T at 6000 kPa

E. NH₃ to MEA Ratio

The ratio of NH₃ to MEA also plays a critical role in optimizing reactor performance. The simulation results showed that the EDA yield improved as the NH₃ to MEA ratio increased, stabilizing at a 1:14 ratio. Ratios beyond this point did not significantly enhance the yield, as the conversion of MEA approached completion (Table 4 and Fig. 10). These findings underline the importance of managing inlet ratios to optimize the overall reaction efficiency.

TABLE IV
NH₃ TO MEA RATIO

Ratio	MEA inlet (kg mole/h)	NH ₃ inlet (kg mole/h)	Product (kg mole/h)	EDA in Product (kg mole/h)	NH ₃ excess (kg mole/h)	Yield	DETA in Product (kgmole/h)
2	4000	8000	12000	3772.800	4113.600	0.943	114.000
3	4000	12000	16000	3784.000	8108.800	0.946	108.800

7	4000	28000	32000	3814.400	24092.800	0.954	92.800
8	4000	32000	36000	3819.600	28090.800	0.955	90.000
9	4000	36000	40000	3824.000	32088.000	0.956	88.000
10	4000	40000	44000	3823.600	36088.800	0.956	88.000
11	4000	44000	48000	3830.400	40084.800	0.958	86.400
12	4000	48000	52000	3832.400	44085.600	0.958	83.200
13	4000	52000	56000	3830.400	48081.600	0.958	84.000
14	4000	56000	60000	3834.000	52080.000	0.959	84.000

F. Performance Achieved in This Research

The simulation results demonstrate that the highest yield of ethylenediamine (EDA), 94.4%, was achieved at optimal operating conditions: a temperature of 150°C, pressure of 6000 kPa, and an ammonia-to-monoethanolamine (NH₃:MEA) molar ratio of 14:1. These conditions also minimized the formation of the primary byproduct, diethylenetriamine (DETA), to negligible levels (<5%). The results indicate that careful control of temperature, pressure, and feed ratios is

critical for enhancing selectivity and efficiency in EDA production.

G. Performance Achieved in This Research

The simulation results demonstrate that the highest yield of ethylenediamine (EDA), 94.4%, was achieved at optimal operating conditions: a temperature of 150°C, pressure of 6000 kPa, and an ammonia-to-monoethanolamine (NH₃:MEA) molar ratio of 14:1. These conditions also minimized the formation of the primary byproduct, diethylenetriamine (DETA), to negligible levels (<5%). The results indicate that

careful control of temperature, pressure, and feed ratios is critical for enhancing selectivity and efficiency in EDA production.

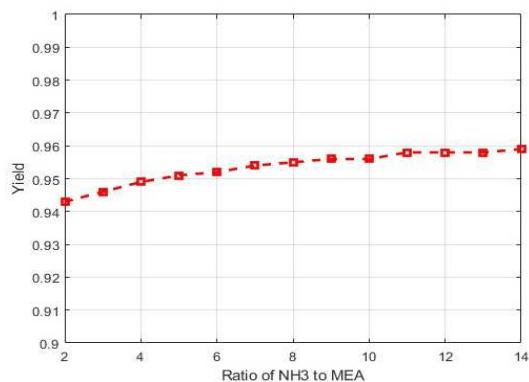

Fig. 10 Plot of Yield vs NH₃ to MEA Ratio

H. Comparison with Previous Studies

The performance metrics obtained in this study are compared to findings from previous research (Table 5) to highlight the improvements and advancements made:

TABLE V
COMPARISON WITH PREVIOUS STUDIES

Parameter	Current study	[21]	Key Differences
EDA Yield (%)	94.4	66.4	Higher yield achieved due to optimal NH ₃ :MEA ratio, temperature, and pressure conditions.
Optimal Pressure (kPa)	6000	8000	Lower pressure improved equilibrium, aligning with Le Chatelier's principle.
Optimal Temperature (°C)	150	170	Lower temperature favored selectivity toward EDA over DETA.
NH ₃ :MEA Ratio	14:1	10:1	Demonstrates the benefit of a higher NH ₃ feed ratio in reducing byproduct formation.

I. Implications for Industrial Scale-Up

The simulation findings have several implications for industrial-scale EDA production. Identifying optimal reactor conditions not only enhances yield but also reduces byproduct formation, leading to a more sustainable and cost-effective process. The ability to fine-tune operating parameters using tools like Aspen HYSYS allows industries to minimize waste and improve overall process efficiency, aligning with the growing focus on sustainable chemical manufacturing.

J. Limitation and Future Work

While the simulation provided valuable insights, the accuracy of the model depends on the assumptions made, such as the reaction kinetics and thermodynamic data used. Future work should focus on experimental validation to ensure that the optimized conditions translate effectively to industrial applications. Further exploration into alternative catalysts and reactor configurations could improve EDA production efficiency.

IV. CONCLUSION

This study provides a comprehensive investigation into optimizing ethylenediamine (EDA) production through the catalytic reaction of monoethanolamine (MEA) and ammonia in a heterogeneous plug-flow reactor (PFR). Utilizing Aspen HYSYS as a simulation tool, the research systematically evaluated key operational parameters, including temperature, pressure, and the ammonia-to-MEA molar ratio, to identify conditions that maximize yield while minimizing byproduct formation.

The findings demonstrate that the optimal conditions—150°C, 6000 kPa, and an ammonia-to-MEA ratio of 14:1—resulted in a maximum EDA yield of 94.4%. These conditions effectively minimize the formation of the byproduct diethylenetriamine (DETA), achieving high selectivity and efficiency. The study highlights the synergistic impact of operational parameter control and catalyst performance on process outcomes, advancing the understanding of heterogeneous catalytic processes for EDA synthesis.

Aspen HYSYS proved instrumental in simulating complex reaction systems and optimizing reactor performance, showcasing its potential as a critical industrial process design and control tool. The insights gained are pivotal for guiding future efforts to scale up EDA production, improve reactor configurations, and explore alternative catalytic systems to enhance sustainability.

Future research should focus on experimental validation of the optimized conditions, developing advanced catalyst formulations, and applying real-time monitoring systems to further refine the production process. By addressing both operational efficiency and environmental impact, this work supports the broader objective of promoting sustainable practices in the chemical manufacturing sector.

Editor in Chief :

Rahmat Hidayat, (Scopus ID: 57191265401) Politeknik Negeri Padang,
 INDONESIA

Associate Editors :

Prof. Taufik, (Scopus ID: 23670809800), California Polytechnic State University,
 USA

Dr. Haitham Alali, (Scopus ID: 49963007000), Amman Arab University, JORDAN

Prof. Wan Mohtar Wan Yusoff, (Scopus ID: 15019967700), Univ. Kebangsaan
 Malaysia, MALAYSIA

Prof. Halimah Badioze Zaman, (Scopus ID: 25825801600), Univ. Kebangsaan
 Malaysia, MALAYSIA

Prof. Son Radu, (Scopus ID: 7005251005), Universiti Putra Malaysia, Malaysia,
 MALAYSIA

Prof. Mohd Razi Ismail, (Scopus ID: 25957691400), Universiti Putra Malaysia,
 MALAYSIA

Prof. Takashi Oku, (Scopus ID: 56275094900), Prefectural University of
 Hiroshima, JAPAN

Prof. Kohei Nakano, (Scopus ID: 7402011766), Gifu University, JAPAN

Dr. Nurul Huda, (Scopus ID: 6701695514), Universiti Malaysia Sabah, MALAYSIA

Dr. Yandra Arkeman, (Scopus ID: 55946558300), Bogor Agriculture University,
 INDONESIA

Prof. Sate Sampattagul, (Scopus ID: 7801640861), Chiangmai University,
 THAILAND

Prof. Peeyush Soni, (Scopus ID: 9248907800), Asian Institute of Technology,
 THAILAND

Dr. Yolanda Lechon Perez, (Scopus ID: 6602826000), Ciemat, Madrid, SPAIN

Prof. Gabriele Arcidiacono (Scopus ID: 56656284600), G. Marconi University,
 ITALY

Prof. Alessandra Pieroni (Scopus ID: 25929524500), Marconi International
 University, Florida - USA

Prof. Alessandro Simonetta (Scopus ID: 55344403700), University of Rome Tor
 Vergata, ITALY

Dr. Rita Muhamad Awang, (Scopus ID: 55957782400), Universiti Putra Malaysia,
 MALAYSIA

Prof. Anton S Prabuwono, (Scopus ID: 18134309800), King Abdulaziz Univ,
 SAUDI ARABIA

Prof. P Mangala C S De Silva, (Scopus ID: 7006461145), University of Ruhuna,
 SRI LANKA

Prof. Bich Huy Nguyen, (Scopus ID: 36191086100), Nong Lam University,
 VIETNAM

Dr. Paul Kristiansen, (Scopus ID: 23097563600), University of New England,
 AUSTRALIA

Prof. Amitava Basu, (Scopus ID: 21833738300), Bidhan Chandra Krishi
 Vidyalya, INDIA

Prof. Shahruh Azman Mohd Noah, (Scopus ID: 35087633200), Universiti
 Kebangsaan Malaysia, MALAYSIA

Prof. Luca Di Nunzio (Scopus ID: 57195199010), University of Rome Tor Vergata,
 ITALY

Prof. Rocco Fazzolari (Scopus ID: 36469997900), University of Rome Tor Vergata,
 ITALY

Dr. Ruben Paul Borg (Scopus ID: 55246483600), L-Università ta' Malta, Msida,
 Malta

Dr. Van Viet Pham (Scopus ID: 57200413784), Ho Chi Minh City University of
 Transport, VIETNAM

Prof. Sergio Spanò (Scopus ID: 57204391824), University of Rome Tor Vergata,

Zhang 3 months ago

Why is the quality of the journal declining every year? Are the editors of this journal primarily focused on profit? It would be beneficial for editors to implement a rigorous manuscript selection process and select high-quality reviewers.

reply

Melanie Ortiz 3 months ago

SCImago Team

Dear Zhang, thanks for your participation! Best Regards, SCImago Team

Agus Haryanto 3 years ago

I see this journal has 51% quartile for engineering and 59% for agriculture since 2021. This mean q2. But in scimagojr still q3. What's wrong?

reply

I

IJASEIT 2 years ago

Dear sir,

Thanks for your question. Actually, it is a normal process in any kind of Journal. It depends on the number of citations, and does not indicate about the quality of journals.

Best - Editorial Board

Melanie Ortiz 3 years ago

SCImago Team

Dear Agus, Thank you for contacting us.

As you probably already know, our data come from Scopus, they annually send us an update of the data. This update is sent to us around April / May every year.

The calculation of the indicators is performed with the copy of the Scopus database provided to us annually. However, the methodology used concerning the distribution of Quartiles by Scopus is different from the one used by SCImago.

For every journal, the annual value of the SJR is integrated into the distribution of SJR values of all the subject categories to which the journal belongs. There are more than 300 subject categories. The position of each journal is different in any category and depends on the performance of the category, in general, and the journal, in particular. The distribution of Quartiles cannot be considered over the journals' total amount within a Category. In the case of SCImago, the distribution has to be considered with the formula Highest-SJR minus Lowest-SJR divided into four.

Best Regards,
SCImago Team

W Warka 3 years ago

Finally, my paper has been published in Vol. 12 (2022) Number 4.

Thank you IJASEIT editor team.

reply

P Projo Danoedoro 3 years ago

I submitted an article to this journal on June 2020 (almost 2 years ago). After 9 months, my paper had been accepted, and I was asked to pay a fee. I paid the fee immediately. However, until now my paper is not published yet, and even other papers that were accepted several months later after mine have been accepted. I have sent emails several times to the editor but until now there is no response.

reply

P Projo Danoedoro 3 years ago

Finally my paper has been published in Vol. 12 (2022) No. 3. I think the Editor has responded my complain properly. I really appreciate it. Thanks a lot ! It's great.

Anyway, my complaint would not come up in this forum if the journal responded my email more quickly, so I suggested that all complaints from the accepted papers' authors should be replied ASAP.

W Warka 3 years ago

I have been waiting for 1,6 years. Until now my paper is not published yet. The Editor said will publish in August 2022.

P Projo Danoedoro 3 years ago

Sorry, I mean "even other papers that were accepted several months later after mine have been PUBLISHED"

Z **Zhanna** 5 years ago

Good day!

Is it Journal in Scopus?

reply

Melanie Ortiz 5 years ago

SCImago Team

Dear Zhanna,

Thank you very much for your comment.

All the metadata have been provided by Scopus /Elsevier in their last update sent to SCImago, including the Coverage's period data. The SJR for 2019 was updated on June 2020, 11th. We suggest you consult the Scopus database directly to see the current index status as SJR is a static image of Scopus, which is changing every day.

Best Regards, SCImago Team

W **Waspoedo Tjipto Subroto** 5 years ago

Dear Elena

Clarify please, what the meaning of coverage 2015-2020?

If coverage 2016-2019, what is this will be discontinued of Scopus indexed, in 2020 ?

Please clarify about coverage in Scimago.

Thanks.
